Table 4. Effect of exposure modality on original and perturbed performance.

Qwen3.5 model	Exposure during training	Epoch 10 (%)		Gap growth ΔG_e (pp)		
		Original	Perturbed	$e = 1$	$e = 3$	$e = 10$
(a) Answer-changing QA: macro accuracy over seven task/dataset pairs						
9B	Same videos, different QA	78.4	66.4	+2.8	+3.2	+5.5
	Evaluation QA, no video	91.9	53.4	+10.3	+21.9	+31.9
	Video + evaluation QA	98.9	54.0	+5.1	+20.7	+38.4
27B	Same videos, different QA	81.4	70.5	+0.7	+0.6	+5.5
	Evaluation QA, no video	98.1	57.5	+14.4	+26.4	+35.2
	Video + evaluation QA	98.4	53.6	+7.5	+18.3	+39.3
(b) Temporal grounding: R@1 at IoU ≥ 0.7 ($N = 5{,}553$)						
9B	Same videos, different QA	22.9	20.4	−0.6	−0.4	+2.5
	Evaluation QA, no video	45.6	13.6	+5.9	+16.1	+32.0
	Video + evaluation QA	70.9	16.0	+3.5	+20.3	+54.9
27B	Same videos, different QA	28.8	20.5	−1.9	+0.0	+8.2
	Evaluation QA, no video	49.2	16.9	+5.3	+13.1	+32.3
	Video + evaluation QA	68.8	16.3	+3.2	+21.1	+52.5

Gap growth. $\Delta G_e = (O_e - E_e) - (O_0 - E_0)$, where O_e and E_e are original and perturbed scores at epoch e. Positive values indicate a widening gap relative to the starting checkpoint; they are descriptive effects, not calibrated detection performance. Values are rounded after calculation.

Exposure and evaluation. All conditions receive video and question at evaluation. QA-only exposure includes evaluation questions and answer targets. Same-video exposure uses different QA. Panel (a) weights each task/dataset pair equally and excludes grounding and both shuffling controls. Panel (b) uses 10% appended black padding for perturbed videos. No independent-run uncertainty is reported.

Starting scores (O_0/E_0). QA: 73.3/66.8% (9B), 75.9/70.4% (27B). Grounding: 18.5/18.5% (9B), 18.4/18.4% (27B).

Task-level exception. For 27B material changes under video+QA exposure, edited accuracy improves from 72% to 86%, while original accuracy rises from 78% to 98%. Gap growth is only +6 pp: exposure does not uniformly reduce perturbed performance.
